This test has 12 pages, be sure your test has them all. Write your NetID clearly on each page of this test and on the front of this test (worth 2 points).

In writing code you do not need to worry about specifying the proper import statements. Don’t worry about getting function or method names exactly right. Assume that all libraries and packages we’ve discussed are imported in any code you write. You can write any helper methods you would like in solving the problems. You should show your work on any analysis questions.

You may consult your six (6) note sheets and no other resources. You may not use any computers, calculators, cell phones, or other human beings. Any note sheets must be turned in with your test.
PROBLEM 1:  (Zeus and a Moon of Jupiter (22 points))

Part A: 8 points
What is printed by each System.out.printf statement? There are four statements, each prints two things.

```java
String s = new String("duke");
String t = s;

String[] a = {"bat", "dog", "cat", "ant", "fox"}
String[] b = a;

s = s + "duke";
a[1] = a[4];

System.out.printf("%s \t %d\n", s, s.length());  // "dukeduke" 8
System.out.printf("%s \t %d\n", t, t.length());  // "duke" 4
System.out.printf("%s \t %s\n", a[1], b[1]);  // "fox" "fox"
System.out.printf("%s \t %s\n", b[4]+a[4], a[4] + b[4]); // "foxfox" "foxfox"
```

Part B: 6 points
The code below prints 3.

```java
23 
24 ArrayList<String> a = new ArrayList<>();
25 String[] array = {"red", "orange", "yellow"};
26 a.addAll(Arrays.asList(array));
27 System.out.println(a.size());
```

Two integers are printed by the code below, which runs immediately after the code above. The first integer printed is 12. Explain why. What is the second integer printed? Explain your answer.

```java
28 for(int k=0; k < 3; k++) a.addAll(Arrays.asList(array));
29 System.out.println(a.size());
30 for(int k=0; k < 3; k++) a.addAll(a);
31 System.out.println(a.size());
```

12 printed since 3 elements added 3 times to an arraylist that starts with 3 elements. 3 + 3x3 = 12

First time 12 elements added to 12-element array list. So a has 24 elements
Next time all 24 added to list with 24, a now has 48 elements
Last time 48 added to list with 48, so 96 elements in a
Part C: 8 points
Write one of: True, False, or cannot be determined. Explain/Justify each answer

- If two string variables s and t have different hash code values, that is \( s-hashCode() \neq t-hashCode() \), then what is the the value of \( s.equals(t) \)?

  False. two strings that are equal must have the same hashcode. So if hashcodes are different strings cannot be equal

- If two string variables s and t have \( s == t \) is true; what is the the value of \( s.equals(t) \)?

  True. if \( s == t \), then s and t label/reference the same object in memory. So the object is equal to itself via .equals since it’s the same object.

- If two string variables s and t have \( s.equals(t) \) is false; what is the value of \( s.hashCode() == t.hashCode() \).

  Cannot be determined. Two different strings can have the same hashCode and this will happen — collisions will occur. If strings are different? then \( s.equals(t) \) will be false. Most different strings do have different hashcodes, but as we saw in class, collisions will occur.

- If two string variables s and t have \( s.equals(t) \) is true; what is the value of \( s == t \).

  Cannot be determined. can have “hello” and “hello” that’s the same location in memory so \( s == t \). Can also have different objects that are both “hello”, in which case \( s \neq t \)
PROBLEM 2 :  (Array Growth (14 points))

In the GrowableStringArray class used in the diyad array assignment two methods were part of adding values to the growable array:

```java
public void add(String s) {
    checkSize();
    myStorage[mySize] = s;
    mySize++;
}

private void checkSize() {
    if (mySize >= myStorage.length) {
        String[] storage = new String[(int) (myStorage.length * 2)];
        System.arraycopy(myStorage, 0, storage, 0, myStorage.length);
        myStorage = storage;
    }
}
```

Two runs are shown below, the size of the array created by adding one element at a time is in the left-most column; the timings from the code shown above are in the middle column; and timings from when * 2 is replaced by * 100 are shown in the right column.

<table>
<thead>
<tr>
<th>array size</th>
<th>* 2</th>
<th>+ 100</th>
</tr>
</thead>
<tbody>
<tr>
<td>100000</td>
<td>0.004</td>
<td>0.093</td>
</tr>
<tr>
<td>200000</td>
<td>0.005</td>
<td>0.570</td>
</tr>
<tr>
<td>300000</td>
<td>0.005</td>
<td>1.243</td>
</tr>
<tr>
<td>400000</td>
<td>0.009</td>
<td>2.203</td>
</tr>
<tr>
<td>500000</td>
<td>0.006</td>
<td>3.504</td>
</tr>
<tr>
<td>600000</td>
<td>0.008</td>
<td>4.878</td>
</tr>
<tr>
<td>700000</td>
<td>0.007</td>
<td>6.970</td>
</tr>
<tr>
<td>800000</td>
<td>0.008</td>
<td>9.141</td>
</tr>
<tr>
<td>900000</td>
<td>0.009</td>
<td>10.224</td>
</tr>
<tr>
<td>1000000</td>
<td>0.013</td>
<td>13.342</td>
</tr>
</tbody>
</table>

Part A (3 points)

Approximately (within ±3) how many times are lines 21-23 executed if the initial size of myStorage is one, and a total of 1,025 elements are added to the array by calling method add shown above 1,025 times and where checkSize uses * 2 when the array grows. Justify briefly.

11 times. The size of the array doubles when its full, so goes from 1,2,4,8,16,32,64,128,256,512,1024 — and then grows again to 2048. Counting the number of times doubling occurs? 11

Note that 2^10 = 1024
Part B (4 points)
The data generating the column on the right uses + 100. If + 100 is replaced by + 1000 will the timings in the last column be less or more than what’s shown for + 100. Explain your answer, be brief.

Each line will be less, it will take less time since array has to grow fewer times to reach a threshold, e.g., to reach 10,000 only grows 10 times instead of 100 times.

Part C (4 points)
The timings in the middle column use * 2. If * 1.25 is used instead will the timings be more similar to the middle column or more similar to the right column? Explain your answer.

More similar to middle column. Still growing at a geometric rate rather than at an arithmetic rate.

Part D (3 points)
In the code for checkSize new array storage is created on line 21. Assume a total of N values are added when myStorage has room initially for one String and * 2 is used to grow the array, as shown.

Using O-notation, what is the total amount of storage created? Justify your answer. If it helps your reasoning, you may assume that \( N = 2^k \) for some \( k \), i.e., that \( N \) is a power-of-two. Recall that in class we noted that \( 1 + 2 + 4 + 8 + \cdots + 2^k = 2^{k+1} - 1 \)

\( O(N) \). We saw this in Part A. to reach 1024 elements, e.g., \( 2^{10} \), the total amount of storage allocated was \( 1+2+4+8+\ldots+512+1024 = 2047 \)

Note that if \( N = 1024 \), then total storage is \( 2*N -1 \) which is \( O(N) \)
The code below is from a version of the CelestialBody class that passes all tests.

```java
public double calcNetForceExertedByX(CelestialBody[] bodies) {
    double s = 0.0;
    for (CelestialBody b : bodies) {
        if (! b.equals(this)) {
            s += calcForceExertedByX(b);
        }
    }
    return s;
}
```

Part A (3 points)
If the expression (! b.equals(this)) is replaced by (! this.equals(b)) will the code still pass all tests? Explain.

Yes, will pass. this.equals(b) has the same truth value as b.equals(this).

Equality is symmetric.

Part B (3 points)
The code calls equals and works correctly for the NBody simulation even though equals is not overridden in the CelestialBody class. Explain why the use of equals works in the simulation even though there is no overridden method.

Default equals compares memory locations. So b.equals(this) is checking that b and this refer to the same object/celestial body. This is what we want in the code.

Part C (3 points)
What type of value is returned by the method calcForceExertedByX?

double
The code for a class `Triangle` is given after the next page as part of this problem – with a complete class definition and a `main` driver. *Be sure to review the code.*

The output of running the program is:

```
[3, 4, 5] 12 6.00
[8, 15, 17] 40 60.0
[10, 10, 12] 32 48.0
```

**Part A (2 points)**

Explain why 12, 40, and 32 are printed as shown above.

The second value printed on each line is the perimeter, these values are the perimeter(s) of each triangle

**Part B (4 points)**

If the statement `new Triangle(10,10,12)` in `main` is replaced by `new Triangle(10,10,20)` the program does *not* print anything other than an error `IllegalArgumentException: bad sides 10 10 20`. What code generates this exception? (reference a line number).

A valid triangle in geometry must have the sum of two sides greater than the maximal/largest side. Explain why testing only `mySideA + mySideB < mySideC` is sufficient and other orderings of sides aren’t needed. Reference code.

It’s line 18, the if statement in the constructor and the throw new … that occurs.

The values of the sides are sorted, so only one check necessary.

**Part C (4 points)**

What is the purpose of the `@Override` annotation for `toString`. Why isn’t `@Override` used before the method `perimeter`?

`@Override` is an indication to the compiler and the software developer that an inherited method is being overridden in this class.

Since `perimeter` is NOT inherited, `@Override` is NOT appropriate.
Part D (4 points)
Assume the method `trianglesFromFile` is uncommented and called from `main`, and the file `triangles.txt` has these six lines:

```
3 4 5
3 4 5
3 4 5
3 4 5
3 4 5
3 4 5
```

The output generated by the call `trianglesFromFile` is as shown. Although all six triangles are the same, the set contains six elements. Explain conceptually why the set contains six `Triangle` objects instead of one triangle object. Reference the method `public boolean equals(Object o)` used by the `Triangle` class. In the next question you’ll rewrite this method.

```java
# triangles = 6
[3, 4, 5]
[3, 4, 5]
[3, 4, 5]
[3, 4, 5]
[3, 4, 5]
[3, 4, 5]
```

Since there is no overridden `.equals` method in the `Triangle` class, the default `.equals` method is called from the `HashSet` class. This checks for object identity, e.g., `s == t`. Since new triangles are created each time, there are six different triangle objects added to the set.

The code in the `HashSet` class treats this as not equal to each other since they are different objects. Note that all six have the same `hashCode`. 
Triangle.java

```java
import java.io.File;
import java.io.FileNotFoundException;
import java.util.*;

public class Triangle {
    private int mySideA;
    private int mySideB;
    private int mySideC;

    public Triangle(int a, int b, int c) {
        int[] sides = {a, b, c};
        Arrays.sort(sides);
        mySideA = sides[0];
        mySideB = sides[1];
        mySideC = sides[2];

        if (mySideA + mySideB <= mySideC) {
            throw new IllegalArgumentException(String.format("bad sides %d %d %d", a, b, c));
        }
    }

    public int perimeter() {
        return mySideA + mySideB + mySideC;
    }

    public double area() {
        double p = perimeter() / 2.0;
        return Math.sqrt(p * (p - mySideA) * (p - mySideB) * (p - mySideC));
    }

    @Override
    public int hashCode() {
        return perimeter() * mySideA;
    }

    @Override
    public String toString() {
        return String.format("%d %d %d", mySideA, mySideB, mySideC);
    }

    public static void main(String[] args) throws FileNotFoundException {
        Triangle[] triangles = {
            new Triangle(3, 4, 5),
            new Triangle(8, 15, 17),
            new Triangle(10, 10, 20),
        };

        for (Triangle t : triangles) {
            System.out.printf("%s\t%d\t%2.3g\n", t, t.perimeter(), t.area());
        }

        //trianglesFromFile();
    }

    public static void trianglesFromFile() throws FileNotFoundException {
        HashSet<Triangle> set = new HashSet<>();
        Scanner scan = new Scanner(new File("data/triangles.txt"));
        while (scan.hasNextInt()) {
            int a = scan.nextInt();
            int b = scan.nextInt();
            int c = scan.nextInt();
            Triangle t = new Triangle(a, b, c);
            set.add(t);
        }
    }
}
```
Part E (4 points)

Complete method equals so it works as intended. If you implement it correctly the code in trianglesFromFile should generate the output below after reading the same data file. The code you write should ensure that two triangles with sides [3,4,5] are equal, but that triangles with sides [3,4,5] and [4,4,4] are not equal. Two triangles are equal when they have three equal sides.

```
# triangles = 1
[3, 4, 5]
```

Complete the method below.

```java
public boolean equals(Object o) {
    if (o == null || ! (o instanceof Triangle)) return false;

    Triangle t = (Triangle) o;

    return mySideA == t.mySideA &&
           mySideB == t.mySideB &&
           mySideC == t.mySideC;

    // Not as good, but acceptable here:
    return toString().equals(t.toString());
}
```
The `main` method shown on the next page is missing statements in the while loop body that will generate the output below. This shows there are 49 two-letter words; 2,235 four-letter words; and 103 16-letter words in the file `wordslower.txt` – a text file of over 45,000 words in the English language.

### Explanation of Code Shown on Next Page

The code uses a map in which keys are integer word lengths and the corresponding value for each key is a list of words with that word length. For example, the statement `System.out.println(map.get(19))` prints three strings in an `ArrayList` as shown:

```
[anthropomorphically, incomprehensibility, straightforwardness]
```

**Part A (2 points)**

Assuming that `wordslower.txt` contains most of the words in the English language, what are two possible words of the 49 words printed by `System.out.println(map.get(2))`?

```
"at", "be", "me", "we", ...
```

**Part B (2 points)**

Why is there output for lines labelled 20, 21, and 22, but then no output for 23-27? Reference the contents of the file `wordslower.txt` in your answer.

There are no words/strings that have 23, 24, 25, 26, or 27 letters.
Part C (6 points)

Complete the while loop so that the code works and generates the output shown above. It’s possible to complete the code with one call of `map.putIfAbsent` and one call of `map.get` with the right parameters, but you can write as many and any lines that result in correct output.

```java
public static void main(String[] args) throws FileNotFoundException {
    File wfile = new File("/data/wordslower.txt");
    Scanner scan = new Scanner(wfile);

    Map<Integer, ArrayList<String>> map = new HashMap<>();

    while (scan.hasNext()) {
        String s = scan.next();
        int len = s.length();
        // add code here

        map.putIfAbsent(len, new ArrayList<>());
        map.get(len).add(s);
    }

    for (int len : map.keySet()) {
        System.out.printf("%d \t%6d\n", len, map.get(len).size());
    }
    scan.close();
}
```
