Indexing

Introduction to Databases
CompSci 316 Fall 2019
Announcements (Mon., Nov. 4)

• **Homework 3** due today
  • Sample solution to be posted on Sakai by this weekend

• **Project milestone 2** due Wed.
  • No Piazza update this week

• **Gradiance indexes** exercise assigned today
  • Due next Monday

• **Homework 4** to be assigned Wed.
What are indexes for?

• Given a value, locate the record(s) with this value
  
  ```sql
  SELECT * FROM R WHERE A = value;
  SELECT * FROM R, S WHERE R.A = S.B;
  ```

• Find data by other search criteria, e.g.
  
  • Range search
    ```sql
    SELECT * FROM R WHERE A > value;
    ```

  • Keyword search

Focus of this lecture
Dense and sparse indexes

- **Dense**: one index entry for each search key value
  - One entry may “point” to multiple records (e.g., two users named Jessica)
- **Sparse**: one index entry for each block
  - Records must be clustered according to the search key
Dense versus sparse indexes

• Index size
  • Sparse index is smaller

• Requirement on records
  • Records must be clustered for sparse index

• Lookup
  • Sparse index is smaller and may fit in memory
  • Dense index can directly tell if a record exists

• Update
  • Easier for sparse index
Primary and secondary indexes

• **Primary index**
  - Created for the primary key of a table
  - Records are usually clustered by the primary key
  - Can be sparse

• **Secondary index**
  - Usually dense

• **SQL**
  - PRIMARY KEY declaration automatically creates a primary index, UNIQUE key automatically creates a secondary index
  - Additional secondary index can be created on non-key attribute(s): `CREATE INDEX UserPopIndex ON User(pop);`
ISAM

• What if an index is still too big?
  • Put a another (sparse) index on top of that!
  
  ISAM (Index Sequential Access Method), more or less

Example: look up 197
Updates with ISAM

Example: insert 107
Example: delete 129

- Overflow chains and empty data blocks degrade performance
  - Worst case: most records go into one long chain, so lookups require scanning all data!
$B^+$-tree

- A hierarchy of nodes with intervals
- Balanced (more or less): good performance guarantee
- Disk-based: one node per block; large fan-out

Max fan-out: 4
Sample B\(^{+}\)-tree nodes

- Max fan-out: 4

Non-leaf

- to keys: 100 ≤ k
- to keys: 100 ≤ k < 120
- to keys: 120 ≤ k < 150
- to keys: 150 ≤ k < 180
- to keys: 180 ≤ k

Leaf

- 120
- 130

- to next leaf node in sequence
- to records with these k values;
or, store records directly in leaves
B\(^{+}\)-tree balancing properties

- Height constraint: all leaves at the same lowest level
- Fan-out constraint: all nodes at least half full (except root)

<table>
<thead>
<tr>
<th></th>
<th>Max # pointers</th>
<th>Max # keys</th>
<th>Min # active pointers</th>
<th>Min # keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-leaf</td>
<td>(f)</td>
<td>(f - 1)</td>
<td>([f/2])</td>
<td>([f/2] - 1)</td>
</tr>
<tr>
<td>Root</td>
<td>(f)</td>
<td>(f - 1)</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>Leaf</td>
<td>(f)</td>
<td>(f - 1)</td>
<td>([f/2])</td>
<td>([f/2])</td>
</tr>
</tbody>
</table>
Lookups

- SELECT * FROM R WHERE $k = 179$;
- SELECT * FROM R WHERE $k = 32$;

Max fan-out: 4

Not found
Range query

- SELECT * FROM R WHERE k > 32 AND k < 179;

Max fan-out: 4

Look up 32...

And follow next-leaf pointers until you hit upper bound
Insertion

• Insert a record with search key value 32

Look up where the inserted key should go...

And insert it right there

Max fan-out: 4
Another insertion example

- Insert a record with search key value 152

Oops, node is already full!
Node splitting

Max fan-out: 4

Oops, that node becomes full!

Need to add to parent node a pointer to the newly created node
More node splitting

- In the worst case, node splitting can “propagate” all the way up to the root of the tree (not illustrated here)
  - Splitting the root introduces a new root of fan-out 2 and causes the tree to grow “up” by one level

Max fan-out: 4

Need to add to parent node a pointer to the newly created node
Deletion

- Delete a record with search key value 130

Look up the key to be deleted...

Max fan-out: 4

If a sibling has more than enough keys, steal one!

Oops, node is too empty!

And delete it
Stealing from a sibling

Remember to fix the key in the least common ancestor of the affected nodes
Another deletion example

- Delete a record with search key value 179

Max fan-out: 4

Cannot steal from siblings
Then coalesce (merge) with a sibling!
Coalescing

- Deletion can “propagate” all the way up to the root of the tree (not illustrated here)
  - When the root becomes empty, the tree “shrinks” by one level

Remember to delete the appropriate key from parent

Max fan-out: 4
Performance analysis

• How many I/O’s are required for each operation?
  • $h$, the height of the tree (more or less)
  • Plus one or two to manipulate actual records
  • Plus $O(h)$ for reorganization (rare if $f$ is large)
  • Minus one if we cache the root in memory

• How big is $h$?
  • Roughly $\log_{\text{fanout}} N$, where $N$ is the number of records
  • $B^+$-tree properties guarantee that fan-out is least $f/2$ for all non-root nodes
  • Fan-out is typically large (in hundreds)—many keys and pointers can fit into one block
  • A 4-level $B^+$-tree is enough for “typical” tables
B⁺-tree in practice

• Complex reorganization for deletion often is not implemented (e.g., Oracle)
  • Leave nodes less than half full and periodically reorganize

• Most commercial DBMS use B⁺-tree instead of hashing-based indexes because B⁺-tree handles range queries
The Halloween Problem

• Story from the early days of System R...

UPDATE Payroll
SET salary = salary * 1.1
WHERE salary >= 100000;
  • There is a B⁺-tree index on Payroll(salary)
  • The update never stopped (why?)

• Solutions?
  • Scan index in reverse, or
  • Before update, scan index to create a “to-do” list, or
  • During update, maintain a “done” list, or
  • Tag every row with transaction/statement id
B⁺-tree versus ISAM

• ISAM is more static; B⁺-tree is more dynamic
• ISAM can be more compact (at least initially)
  • Fewer levels and I/O’s than B⁺-tree
• Overtime, ISAM may not be balanced
  • Cannot provide guaranteed performance as B⁺-tree does
B⁺-tree versus B-tree

• B-tree: why not store records (or record pointers) in non-leaf nodes?
  • These records can be accessed with fewer I/O’s

• Problems?
Beyond ISAM, B-, and B\(^+-\)trees

• Other tree-based indexes: R-trees and variants, GiST, etc.
  • How about binary tree?

• Hashing-based indexes: extensible hashing, linear hashing, etc.
• Text indexes: inverted-list index, suffix arrays, etc.
• Other tricks: bitmap index, bit-sliced index, etc.
