Solving Problems Recursively

- **Recursion is an indispensable tool in a programmer’s toolkit**
  - Allows many complex problems to be solved simply
  - Elegance and understanding in code often leads to better programs: easier to modify, extend, verify (and sometimes more efficient!!)
  - Sometimes recursion isn’t appropriate, when it’s bad it can be very bad---every tool requires knowledge and experience in how to use it

- The basic idea is to get help solving a problem from coworkers (clones) who work and act like you do
  - Ask clone to solve a simpler but similar problem
  - Use clone’s result to put together your answer

- Need both concepts: call on the clone and use the result
Print words entered, but backwards

- Can use a vector, store all the words and print in reverse order

- The vector is probably the best approach, but recursion works too

```java
void printReversed() { // some I/O details omitted
    String word;
    word = console.readLine();
    if (word.length() > 0) { // get something?
        printReversed(); // print the rest reversed
        System.out.println(word); // then print the word
    }
}

// somewhere in main
---.printReversed();
```

- The function `printReversed` reads a word, prints the word only after the clones finish printing in reverse order
- Each clone has its own version of the code, its own `word` variable
Exponentiation

- Computing $x^n$ means multiplying $n$ numbers (or does it?)
  - What’s the easiest value of $n$ to compute $x^n$?
  - If you want to multiply only once, what can you ask a clone?

```java
double power(double x, int n)
// post: returns $x^n$
{
    if (n == 0)
    {
        return 1.0;
    }
    return x * power(x, n-1);
}
```

- What about an iterative version?
Faster exponentiation

- How many recursive calls are made to compute $2^{1024}$?
- How many multiplies on each call? Is this better?

```c
double power(double x, int n)
// post: returns $x^n$
{
    if (n == 0) {
        return 1.0;
    }
    double semi = power(x, n/2);
    if (n % 2 == 0) {
        return semi*semi;
    }
    return x * semi * semi;
}
```

- What about an iterative version of this function?
Keys to Recursion

- **Recursive functions have two key attributes**
  - There is a *base case*, sometimes called the *halting or exit case*, which does **not** make a recursive call
    - See print reversed, exponentiation, factorial for examples
  - All other cases make a recursive call, with some parameter or other measure that decreases or moves towards the base case
    - Ensure that sequence of calls eventually reaches the base case
    - "Measure" can be tricky, but usually it’s straightforward

- **Example: sequential search in a vector**
  - If first element is search key, done and return
  - Otherwise look in the “rest of the vector”
  - How can we recurse on “rest of vector”?
Classic examples of recursion

- **For some reason, computer science uses these examples:**
  - Factorial: we can use a loop or recursion. Is this an issue?
  - Fibonacci numbers: 1, 1, 2, 3, 5, 8, 13, 21, …
    - F(n) = F(n-1) + F(n-2), why isn’t this enough? What’s needed?
    - Classic example of bad recursion, to compute F(6), the sixth Fibonacci number, we must compute F(5) and F(4). What do we do to compute F(5)? Why is this a problem?
  - Towers of Hanoi
    - N disks on one of three pegs, transfer all disks to another peg, never put a disk on a smaller one, only on larger
    - Every solution takes “forever” when N, number of disks, is large
Fibonacci: Don’t do this recursively

```java
long recFib(int n) {
    // precondition: 0 <= n
    // postcondition: returns the n-th Fibonacci number
    if (0 == n || 1 == n) {
        return 1;
    } else {
        return recFib(n-1) + recFib(n-2);
    }
}
```

How many clones/calls to compute F(5)?

How many calls of F(1)?

How many total calls?

consider caching code

CompSci 100E
Towers of Hanoi

- The origins of the problem may be in the far east
- Move $n$ disks from one peg to another in a set of three

```java
void move(int from, int to, int aux, int numDisks)
    // pre: numDisks on peg # from,
    //      move to peg # to
    // post: disks moved from peg 'from' // to peg 'to' via 'aux'
{
    if (numDisks == 1) {
        System.out.println("move " + from + " to " + to);
    } else {
        move(from, aux, to, numDisks - 1);
        move(from, to, aux, 1);
        move(aux, to, from, numDisks - 1);
    }
}
```
What’s better: recursion/iteration?

- There’s no single answer, many factors contribute
  - Ease of developing code assuming other factors ok
  - Efficiency (runtime or space) can matter, but don’t worry about efficiency unless you know you have to

- In some examples, like Fibonacci numbers, recursive solution does extra work, we’d like to avoid the extra work
  - Iterative solution is efficient
  - The recursive inefficiency of “extra work” can be fixed if we remember intermediate solutions: instance variables

- Instance variable: maintains value over all function calls
  - Local variables created each time function called
Fixing recursive Fibonacci

```java
long[] storage = new long[31];
long recFib(int n) {
  // pre: 0 <= n <= 30
  // post: returns the n-th Fibonacci number
  Arrays.fill(storage, 0);
  return recF(n);
}
long recF(int n) {
  if (0 == n || 1 == n) return 1;
  else if (storage[n] != 0) return storage[n];
  else {
    storage[n] = recF(n-1) + recF(n-2);
    return storage[n];
  }
}
```

- What does storage do? Why initialize to all zeros?
  - Instance variables initialized first time function called
  - Maintain values over calls, not reset or re-initialized
Thinking recursively

- **Problem: find the largest element in a vector**
  - Iteratively: loop, remember largest seen so far
  - Recursive: find largest in [1..n], then compare to 0th element

```c
double max(double[] a)
// pre: a contains a.length elements, 0 < a.length
// post: return maximal element of a
{
    int k;
    double max = a[0];
    for(k=0; k < a.size(); k++) {
        if (max < a[k]) max = a[k];
    }
    return max;
}
```

- In a recursive version what is base case, what is measure of problem size that decreases (towards base case)?
Recursive Max

double recMax(double[] a, int first)
// pre: a contains a.length elements, 0 < a.length
// first < a.length
// post: return maximal element a[first..length-1]
{
    if (first == a.length-1){ // last element, done
        return a[first];
    }
    double maxAfter = recMax(a, first+1);
    if (maxAfter < a[first]) return a[first];
    else return maxAfter;
}

- What is base case (conceptually)?
- We can use recMax to implement max as follows
  return recMax(a, 0);
Recognizing recursion:

```java
void change(int[] a, int first, int last)
// post: a is changed
{
    if (first < last)
    {
        int temp = a[first];  // swap a[first], a[last]
        a[first] = a[last];
        a[last] = temp;
        change(a, first+1, last-1);
    }
}
// original call (why?): change(a, 0, a.length-1);
```

- What is base case? (no recursive calls)
- What happens before recursive call made?
- How is recursive call closer to the base case?
More recursion recognition

```java
int value(int[] a, int index) {
    // pre: ??
    // post: a value is returned
    if (index < a.length) {
        return a[index] + value(a, index+1);
    }
    return 0;
}
// original call: val = value(a, 0);
```

- What is base case, what value is returned?
- How is progress towards base case realized?
- How is recursive value used to return a value?
- What if a is vector of doubles, does anything change?
Grades, vectors, matrices

double[][] grid = new double[20][30];
for(int k=0; k < grid.length; k++){
    grid[k][5] = 4.0;
}

How is # rows specified? Columns?

- How do we set row with index 8 to have value 2.0?
  
  for(int k=0; k < grid[0].length; k++){
      grid[8][k] = 2.0;
  }

 Thirty columns

Twenty rows

Blob Counting: Recursion at Work

- Blob counting is similar to what’s called Flood Fill, the method used to fill in an outline with a color (use the paint-can in many drawing programs to fill in)
  - Possible to do this iteratively, but hard to get right
  - Simple recursive solution

- Suppose a slide is viewed under a microscope
  - Count images on the slide, or blobs in a gel, or ...
  - Erase noise and make the blobs more visible

- To write this program we’ll used a class CharBitMap which represents images using characters.
Counting blobs, the first slide

prompt> blobs
enter row col size 10 50
# pixels on: between 1 and 500: 200

+--------------------------------------------------+
| * * * * * *** * **** * * || * * *** ** ** * * * * * * *|| * *** * * *** * * * * * * * * **|
| * ** ** * ** * * * *** * * |
| * * ***** *** * * ** ** * ||* * * * * * ** * *** * *** *||* * *** * ** * * * * * ** |
|* * ** * * * * *** ** * |
| **** * * ** **** * *** * * **||** * * * ** **** ** * * ** *|+--------------------------------------------------+

How many blobs are there? Blobs are connected horizontally and vertically, suppose a minimum of 10 cells in a blob

- What if blob size changes?
Identifying Larger Blobs

blob size (0 to exit) between 0 and 50: 10

# blobs = 3

- The class **Blobs** makes a copy of the **CharBitMap** and then counts blobs in the copy, by erasing noisy data (essentially)
  - In identifying blobs, too-small blobs are counted, then uncounted by erasing them
Identifying smaller blobs

blob size (0 to exit) between 0 and 50: 5

88....................8............................77.7777

# blobs = 8

❖ What might be a problem if there are more than nine blobs?

- Issues in looking at code: how do language features get in the way of understanding the code?
- How can we track blobs, e.g., find the largest blob?
Issues that arise in studying code

- **What does static mean, values defined in Blobs?**
  - Class-wide values rather than stored once per object
  - All Blob variables would share `PIXEL_OFF`, unlike `myBlobCount` which is different in every object
  - When is static useful?

- **How does the matrix work**
  - Two-dimensional array
  - First index is the row, second index is the column

- **We’ll study these concepts in more depth, a minimal understanding is needed to work recursive blob find**
Recursive helper functions

- Client programs use `findBlobs` to find blobs of a given size in a `CharBitMap` object
  - This is a recursive function, private data is often needed/used in recursive method parameters
  - Use a helper function, not accessible to client code, use recursion to implement member function

- To find a blob, look at every pixel, if a pixel is part of a blob, identify the entire blob by sending out recursive clones/scouts
  - Each clone reports back the number of pixels it counts
  - Each clone “colors” the blob with an identifying mark
  - The mark is used to avoid duplicate (unending) work
Conceptual Details of BlobFill

- Once a blob pixel is found, four recursive clones are “sent out” looking horizontally and vertically, reporting pixel count
  - How are pixel counts processed by clone-sender?
  - What if all the clones ultimately report a blob that’s small?

- In checking horizontal/vertical neighbors what happens if there aren’t four neighbors? Is this a potential problem?
  - Who checks for valid pixel coordinates, or pixel color?
  - Two options: don’t make the call, don’t process the call

- Non-recursive methods takes care of looking for blobsign, then filling/counting/unfilling blobs
  - How is unfill/uncount managed?
Saving blobs

- In current version of `findBlobs` the blobs are counted
  - What changes if we want to store the blobs that are found?
  - How can clients access the found blobs?
  - What is a blob, does it have state? Behavior?
  - What happens when a new minimal blob size is specified?
