Shorter of two objects and changing color V2

Functions, events and setting the color in sequence and randomly

This is a modification of the Changing Color tutorial by Susan Rodger in July 2009
By Erin Taylor and David Yan
Under the direction of Susan Rodger
Duke University
June 2015

What this tutorial shows

• You’ve used built-in functions. Now you will write your own functions.

• NOTES: Not all objects can change color. The chicken and snowman can change color, which is why we use them. The bunny cannot change color, the object was just designed that way.

Parts

• Part 1: Create a “world” function that returns the shorter of two objects – make it a world function because it uses two different objects
• Part 2: Create a chicken function that returns a color (cycling through 4 colors) and use the function to change the color of the chicken
• Part 3: Create a snowman function that returns a random color and use the function to change the color of the snowman randomly
• Part 4: Create a snowman function to return the color as a word and use the function to have the snowman say what color it is.

Part 1: Start Alice world with sand and add in chicken, snowman, bunny, and joey
Create World function “ObjectThatIsShorter” – select Type as Object

The new function appears – notice the “Obj” – means this function returns an object

What this function will do

- A function computes an answer and returns the answer.
- The function ObjectThatIsShorter will compare the chicken and the snowman in height and the answer is the one that is shorter. The function returns the shorter object.
- Since the function type is “object” the function must return an “object”

Drag up if/else
Compare chicken and snowman’s heights – from world functions, drag over the “a<b” into the “true” and enter 1’s.

Now click on Chicken, then functions, and drag “Chicken’s height” over twice.

Click on the second “Chicken” and change to “snowman”.

Drag up “return” and select Chicken.

Compute the answer

• If the chicken’s height is less than the snowman’s height, then we know the answer is the Chicken. The “answer” is put in the line after the “if” and before the “else” (see the next slide).
• To return the answer, drag up “Return” from the bottom of the window (see the next slide).
If Chicken is taller than snowman

- Then the answer (or shortest object) is snowman
- After the “else” return snowman

Note that the answer is either the “chicken” or the “snowman”, but not both. Only one of the two is returned.

Now try out the function, use it where there is an object.
In myFirstMethod, put this code...

Replace “chicken” with new function – in World Functions, drag over the function “objectThatIsShorter” (that returns an object) over Chicken.

objectThatIsShorter can be used in place of any object.
Click Play

• Only the Chicken and snowman’s height are compared and the one that is shorter (the chicken) says “I’m shorter!”

• Does your function really work? Resize the chicken so it is larger than the snowman and then play again. This time the snowman should say “I’m shorter!”

Adding Flexibility

• We wrote the function to compare the chicken and snowman’s heights.
• For Example, notice that with the “move” command, it is flexible in that you get to pick the direction and the distance to move.
• To make this function more flexible, we will add two parameters (choices, so you can pick the two objects to compare).

Enter the name “object1” and select type “Object”
Add another parameter named “object2” of type “Object”

Click and drag “object1” over both Chickens

Click and drag object2 on top of both of the snowman’s

Now let’s Test the method
- Back in myfirstmethod, note that now you have to choose two objects to compare in the function objectThatIsShorter.
- Select two animals and Play.
- Then select two different animals and play again
Resize objects to make some taller, and click Play again

Part 2: Change the color of the chicken from “no color” to “blue” to “red” to “green” and cycle through again

Create Chicken Function “changeColor”
Click on Chicken, then functions, then “create new function”, type “changeColor” as name, and type “Color”

The new function appears – notice the color wheel – this function returns a new color
Returning new Chicken color - Idea

- If the chicken color is “no color” then we want to return the new color “blue”
- Else, if the chicken color is “blue”, then we want to return the new color “red”
- Else, if the chicken color is “red”, then we want to return the new color “green”
- Else if the chicken color is “green”, then we want to return the new color “no color”

The “no color” when dropped looks like white. Now drag up “return”, drop in after the if, and select “Blue”

First Drag up the if/else. Then select “Chicken”, “properties”. Then drag over the color property into “true” and select “Chicken.color == no color”

Under the “else” part, drag in another if/else, and repeat the second if (if the color is blue, return red)
Now continue with two more colors

- If the chicken color is red, return green
- Else, return “no color”

Now, let’s use the new function `Chicken.changeColor`. When we click on a Chicken we will change its color to the new color returned from this function. First create an event.
First, select Chicken to click on, then drag over color property and under expressions, pick the color returned by the function `chicken.changeColor`.

Here is the final event:

- **When the world starts**, do `world.my first method`.
- **When `Chicken` is clicked on**, do `Chicken set color to Chicken.changeColor`.

Now click Play and then click on the chicken several times.

Part 3

- Now we will write a function to return a random color and use that color to change the color of the snowman.
Click on Snowman, functions, then create new function, with name changeColorRandom and type color.

How to change color randomly:

- Generate a random integer in Alice between 1 and 4 (inclusive)
- If the number is 1, return color “red”
- Else, if the number is 2, return “blue”
- Else if the number is 3, return “green”
- Else if the number is 4, return “no color”

First, create a “local variable” called colorNumber to store the random number, this is like a “property” for the function. Make sure to select Type: number.

1. The local variable appears
2. Drag it down to the code and set its value to 1.
Select “world”, then “functions” to find “random number”, and drag it over the “1”

Click on “more” to add minimum set to 1 and maximum set to 5. colorNumber stores the random number generated so we can refer to it.

Now click on “more,” select integerOnly, and change it to true. This will now randomly generate integers instead of decimals. *Note that the only values you will get are 1, 2, 3, or 4 because lower bound is inclusive and the upper bound is exclusive.

Drag up an if/else.
Check colorNumber for red case:
   If colorNumber == 1
from “world”, “functions”, drag over a==b, then fill in with “colorNumber” == “1”

Drag up the return, and select the color red

Drag another if/else into the else, and drag in code for the “blue” case.

Add “green” and “no color” cases
Create and event for clicking on snowman, then drag snowman’s color property over.

Click “Play” and click on the snowman and he randomly selects one of the four colors.

How do you know if it is working correctly? Drag up print to see the colorNumber value. Select Object, camera

Drag colorNumber over “camera”. 
Click on down white arrow and type in text: “Value of colorNumber is “

Now play, click on snowman and you can see the value of colorNumbers to see if the colors match its corresponding integer.

Part 4

• Write a function to return the current color of the snowman, as a word. We will use the word to have the snowman say what color he is.

Create getNameOfColor

• Click on “snowman”, then “functions” tab, then “create new function”. Enter the name “getNameOfColor” and select type “String”
Resulting function ... Note return type is “ABC” for a word (or String)

Drag up an if-else

- Then click on “snowman”, then properties tab. Drag over the “color” into the “true” and select “snowman’s color == red”

Result is:

Drag up “Return” tab from the bottom and enter the value “red”
Add additional if’s for the other three color cases – here is the Blue case

```plaintext
If snowman.color == red
    Return red

Else
    If snowman.color == blue
        Return blue

Else
    Do Nothing
```

Here is the code after adding the green and white (default) cases

```plaintext
If snowman.color == red
    Return red

Else
    If snowman.color == blue
        Return blue

Else
    If snowman.color == green
        Return green

Else
    Return white
```

Now let’s use the new function

• Let’s change the event

```plaintext
When snowman is clicked on
    Do in order
        snowman.set color to snowman.setColorRandom
```

• To this:

```plaintext
When snowman is clicked on
    Do in order
        snowman.set color to snowman.setColorRandom
        snowman.say I’m the color more... 
```

By copying the “snowman set color” line to the clipboard, then drop in a “do in order”, paste the “snowman set color back in”

Now drag in “snowman say”

• And have the snowman say “I’m the color “ and make sure you put a blank after the word color.
Join in the name of the color

- Click on “world” “functions” and drag over the “a joined with b”, and drop that on what the snowman is saying, select “expressions” and the “getNameOfColor” function

Resulting code. Now Play and click on snowman, he tells you his color!
